37 This dissertation will be abstract.

Chapter 1

Introduction

In this chapter we give a brief overview of autonomous navigation and the small unmanned ground vehicles (UGVs) that will be considered in this thesis. We also describe some of the issues in state estimation and controls that were considered during research in improving the autonomous driving behaviors of the UGVs.

1.1 The Need for Autonomy

Robots have been developed to assist humans in tasks that are generally considered dirty, dangerous or boring. Recently robots have found a useful niche as a tool to help Explosives Ordinance Disposal (EOD) teams to assess and eliminate threats due to improvised explosive devices (IEDs), commonly referred to as roadside bombs, by allowing humans to maintain a safe stand-off distance while investigating a scene. Clearly this falls under the dangerous category. The current method that EOD teams use involves teleoperation of the robot to get from the base to the object of interest. In the process of teleoperating the robot the operator is exposed and vulnerable to other external threats in the area. As technologies mature to provide humans with better tools shortcomings are discovered, such as the vulnerability due to teleoperation, and that opens up avenues for improvement in the development of these tools. For robots one approach to reducing the amount of work humans are required to perform is to give the robots more intelligence via autonomous behaviors using additional sensors, more specialized actuators and

59 software to automate the largest amount of routine tasks as possible.

60 When adding autonomy to robots nearly all of the tasks can be summarized by
61 the following questions:

- 62 • Where am I?
- 63 • What's around me?
- 64 • Where do I want to go?
- 65 • How do I get there?

66 Other tasks for small UGVs include sending them into buildings that are
67 dangerous due to structural damage or unknown, possibly hostile elements inside so
68 that the robots can map the interior and additionally to provide human operators
69 with images to assess the danger prior to any humans entering the buildings [Con 06].
70 After the attacks on the World Trade Center on September 11, 2001 several small
71 UGV systems were used to look for survivors in the rubble and to help assess
72 structural damage to nearby buildings [Everett 02].

73 The initial attempt at adding autonomy to the EOD robots resulted in somewhat
74 erratic driving behavior, especially near obstacles, as the robot trajectory would
75 not be smooth as it changed speed and attempted to make small corrections to its
76 original path to move around the obstacle. In this thesis we will look at smoothing
77 out the trajectories taken by the robot by looking for improvements in the state
78 estimation (Where am I?) and controls (How do I get there?) algorithms. This
79 work ignores actual obstacle detection (What's around me?) and will be using a
80 simple planning algorithm (Where do I want to go?) to simulate obstacles in the
81 robot path which will force the robot to change direction and speed multiple times.

82 *** Talk about how speed and efficiency are important characteristics of robots
83 in their typical operating environments and that improved navigation would improve
84 the speed and efficiency. An example is less time waiting to get robot close to IED
85 or to clear a building means less time for humans in hostile environment. In search
86 and rescue situations this would lead to less time for searching and more time for
87 rescuing. ***

88 1.2 Thesis Outline & Contributions

89 The problem of autonomous navigation is not isolated to any one technical area
90 but is instead a combination of sensor integration to allow the robot position and
91 obstacles to be observable, noise filtering, state estimation and control algorithms.
92 As much as possible this research has attempted to isolate the effects of each of
93 those areas to enable a quantitative analysis to determine which parts of the system
94 contribute the largest effect on overall robot behavior.

95 Chapter 2 gives some background on the types of robots used, the sensors on
96 the robots and the operator control unit (OCU). Chapter 3 presents the state
97 estimation algorithm that is used on the robots. Chapter 4 discusses the original
98 control algorithm and a new control algorithm applied as part of this research.
99 Chapter 5 gives the results of experiments run with the robots and looks at the
100 main contributing factors for smooth autonomous navigation. Chapter 6 suggests
101 future avenues of research to pursue. The conclusion is found in Chapter 7.

102 The main contribution of this research is that the small UGVs investigated
103 here have greater autonomy which will allow for less human oversight of basic
104 functionality. This is especially important for the dirty, dangerous and boring tasks
105 that robots where robots are most useful because it allows the humans to focus
106 their concentration, time and effort on clean, safe and efficient.

107 Chapter 2

108 Background

109 *** Put in a description of the PackBot, Talon and Urbot along with a description
110 of the algorithms originally used and the results obtained using those algorithms.
111 Talk about JAUS and MOCU a little bit. Discuss more about how the robots are
112 used by EOD. Include that for robots to drive around on their own all they require
113 is an estimate of where they are, a path to follow, a controller to determine the
114 actuator outputs and motor controllers to perform the controller outputs. ***
115 *** It might be best to have more of a description of the actual problem here
116 along with a description of the testing area. ***

117 2.1 Small Unmanned Ground Vehicles

118 The PackBot is manufactured by iRobot. *** Add more. ***
119 The Talon is manufactured by Foster Miller. *** Add more. ***
120 The Urbot was an experimental prototype created at SSC-SD. *** Add more.
121 ***

122 2.2 MOCU & JAUS

123 The Multi-Robot Operator Control Unit (MOCU) is a highly configurable front-
124 end for simultaneous command and control of multiple systems and was created
125 at SSC-SD [Powell 08]. MOCU has the ability to use a variety of communications

126 protocols for interfacing to different systems and uses the Joint Architecture for
 127 Unmanned Systems (JAUS) to send and receive data to all of the UGVs used in
 128 this research [Rowe 08].

129 **2.3 The Duals: Estimation & Controls**

130 It is very difficult to simply work on either state estimation or controls indi-
 131 vidually as there is a large amount of coupling between the two areas. Although
 132 the main goal is to make the robots drive more smoothly and that the actuator
 133 and motor outputs are ultimately generated by the control system it is still the
 134 case that the role of state estimation is equally important. If there exists large
 135 measurement errors, drift or bias in the sensor readings then the robot will not have
 136 a very good idea of where it is located and there will not be a controller that can
 137 stabilize the system. *** Talk about observability and controllability. Mention
 138 theory that shows link between estimation and control. ***

139 An example would be when the only sensor available for measurements is an
 140 IMU which suffers from drift and bias, where both effects are exaggerated by
 141 temperature. There have been situations in which an IMU was in a robot with the
 142 motors turned off so that the robot is not moving. However, due to excessive heat
 143 in the electronics box the IMU measurements report that the heading of the robot
 144 keeps moving in circles at a rate of $\frac{\pi}{5} rad/s$. With a controller that was known to
 145 keep the robot stable when the IMU was working properly started forcing the robot
 146 to turn in circles when the motors were turned on even though the command was
 147 to stay in one place. This shows the importance of state estimation on overall robot
 148 performance – it is not enough to only have a good controller.

149 Chapter 3

150 State Estimation

151 *** Talk about quantifying the performance of the ACS Kalman filter [Sights 06].
152 Discuss training of the covariance matrices. Show the position estimation using the
153 original covariance matrices and the ones found from training. If I get to identifying
154 bias and/or drift in the IMU put that here as well. ***

155 The Space and Naval Warfare Systems Center, San Diego (SSC-SD) robotics
156 group has developed the Autonomous Capabilities Suite (ACS) which incorporates
157 many different technologies into a single software package that can be run on a
158 wide variety of different robots and is able to easily accomodate different payload
159 and sensor suites [Sights 06]. One of the ACS libraries is the adaptive extended
160 Kalman filter which is used on the EOD robots for state estimation and is the
161 main method used for answering the question “Where am I?”. The idea behind
162 the Kalman filter is relatively straightforward. The robot has some basic idea of
163 where it is in the world but there is some uncertainty involved in that estimate due
164 to different measurement accuracies from multiple sensors that measure the same
165 state, noise in the individual sensor measurements and an imperfect model of how
166 the robot moves through the world. Some of the uncertainty of the model can be
167 explained by the fact that not all of the necessary measurements are being carried
168 out and the states can be unobservable. *** Say more here about noise/uncertainty.
169 ***

170 An example is a robot driving in a straight line where the left track may be
171 moving on a flat surface while the right track is moving on an uneven surface as

172 in Figure 3.1. The wheel encoders that measure how far each track is moving will
 173 report that the right track is traveling a greater distance than the left track which
 174 could mean that the robot is turning counter-clockwise or that the robot tracks are
 175 moving over different surface types. At the same time the robot will be getting
 176 measurements about its heading from both the IMU and GPS sensors that will
 177 have some noise as well. In this example both the IMU and GPS sensors would
 178 likely say that the robot is traveling in a straight line on average (as long as the
 179 controller is performing adequately). The job of the Kalman filter is to determine
 180 how much each sensor should be trusted when trying to determine where the robot
 181 really is in the world and how fast it is moving. This is accomplished by looking at
 182 each of the noise parameters for both the system model and the measurements as
 183 being zero mean, white noise, uncorrelated, Gaussian variables ... *** Clean up
 184 this language. Consider putting it in a different section. ***

Figure 3.1: Different topographies for the left track and the right track when the ground is smooth on the left side and bumpy on the right side. The top line is for the left track and the bottom line is for the right track.

185 3.1 State Space Models

186 Kalman filters and control systems (see Chapter 4) use the idea of a multi-
 187 dimensional state space to encapsulate all of the relevant information that is known
 188 about a system. In the case of robots the dynamics are typically captured by
 189 position, orientation, linear and angular velocities, acceleration and sometimes jerk.
 190 The standard equations to describe the state space of a system are

$$\begin{aligned}\dot{x} &= f(x, u, t) \\ \dot{y} &= h(x, t)\end{aligned}\tag{3.1}$$

191 The state variables are given in vector form by x and the sensor measurements
 192 are contained in the vector y . The state space equations are a means of representing
 193 how the state and measurements of a system change through time based on the
 194 initial state of the system and the inputs, u , to the system which allows the trajectory
 195 (or motion through time) and the effect of the trajectory on the measurements
 196 to be calculated using compact notation. The inputs are assumed to include any
 197 external forces applied to the system as well as actuation provided by the system
 198 itself.

199 3.2 The Kalman Filter

200 The ACS Kalman filter is typical of all Kalman filters in that it consists of
 201 a prediction update step and a measurement update step where the prediction
 202 update is run as fast as possible and the measurement update is run whenever
 203 new sensor data becomes available as in Figure 3.2. The prediction update step
 204 uses the model of the dynamics of the system and a measurement of elapsed time
 205 to determine where the system is in the world. The measurement update step is
 206 basically a feedback step to help correct for errors in the system model [Kelly 94].
 207 From [Kelly 94], [Simon 06] the prediction update step marches the system
 208 dynamics forward in time using the equations

$$\begin{aligned}\hat{x}_{k+1}^- &= \Phi_k \hat{x}_k \\ P_{k+1}^- &= \Phi_k P_k \Phi_k^T + \Gamma_k Q_k \Gamma_k^T\end{aligned}\tag{3.2}$$

209 and the measurement update step provides feedback from sensor data using the
 210 equations

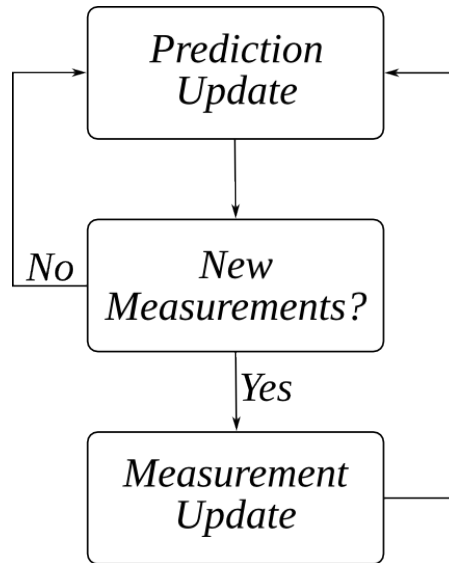

Figure 3.2: The Kalman filter algorithm.

$$\begin{aligned}
 K_k &= P_k^- H_k^T [H_k P_k^- H_k^T + R_k]^{-1} \\
 \hat{x}_k &= \hat{x}_k^- + K_k [z_k - H_k \hat{x}_k^-] \\
 P_k &= [I - K_k H_k] P_k^-
 \end{aligned} \tag{3.3}$$

211 The state space equations for the robot are

$$\begin{aligned}
 x_{k+1} &= \Phi_k x_k + \Gamma_k w_k \\
 z_k &= H_k x_k + v_k
 \end{aligned} \tag{3.4}$$

212 3.3 Adaptive Extended Kalman Filter

213 *** I really need to clean up the language here. [Busse 03] looks like a great
 214 source. Even the notation as far as *a priori* and *a posteriori* needs fixing. ***
 215 Attempting to determine the proper values for the covariance matrices Q in (3.2)
 216 and R in (3.3) can be a laborious process and is often considered more of an
 217 art than a science with engineer experience being a critical factor. *** Discuss
 218 why Q and R are important and what function they serve in the Kalman filter.

219 *** The ACS Kalman filter has been implemented with an adaptive scheme to
 220 update the covariance matrices in real time as the robot moves around and sensor
 221 measurements are taken into account [Sights 06], [Mehra 72], [Busse 03]. Q and R
 222 are updated at alternating time steps in the EKF.

223 The first step is to calculate Q^* using

$$Q^* = (x - x_{k+1}^-) (x - x_{k+1}^-)^T + P_{k+1}^- - P - Q \quad (3.5)$$

224 Then Q can be updated using

$$Q = Q + \frac{1}{L_Q} (Q^* - Q) \quad (3.6)$$

225 Next R^* is calculated using

$$R^* = (y - Hx) (y - Hx)^T - HP_{k+1}^- H^T \quad (3.7)$$

226 and R can be updated using

$$R = R + \frac{1}{L_R} (R^* - R) \quad (3.8)$$

227 *** Discuss the implications of the adaptive EKF. ***

228 3.4 Discriminative Training of Kalman Filter Pa- 229 rameters

230 *** Investigate the difference between adaptive filtering and training. It seems
 231 like they accomplish the same thing, namely, convergence to some values for the
 232 covariance matrices. Do they use the same metrics? Do they converge to the

233 same covariance matrices? Is it just online vs. offline training? *** [Abbeel 05]
234 describes a method to automatically learn what the covariance matrices should
235 be. When used in conjunction with the adaptive EKF scheme this could allow for
236 faster convergence times when the robots are started and for smaller ranges for the
237 adaptation coefficients L_Q and L_R in (3.6) and (3.8).

238 3.5 Identify IMU Parameters

239 Chapter 4

240 Controls

241 *** Talk about Lyapunov and PID controllers. ***

242 4.1 PID

243 *** Talk about how PID controllers work. Discuss the difficulties of tuning the
244 PID controllers. ***

245 4.2 Lyapunov

246 *** Talk about how Lyapunov controllers work [Khalil 02]. Show which control
247 Lyapunov function I chose [Rusu 05]. For a given path show the linear and angular
248 velocities that are output by each controller. ***

249 Chapter 5

250 Results

251 *** I want to show plots with the position estimate using GPS only, KF with
252 learned Q/R but no adapting, KF with no adapting or training, KF with adapting,
253 KF with learned and adaptive, KF with different encoder equations. Would be
254 cool to plot these on an overhead image of the test area. ***

255 *** I want to show plots of the variance of the KF position estimate and the
256 derivative of the control outputs of linear and angular velocity. The real goal is to
257 have smooth velocities which will show up as constant accelerations and I want to
258 see if there is any correlation between the variance of the position estimate and
259 the accelerations, especially when the variance of the position estimate has a large
260 amplitude. This would indicate that the controller is not necessarily doing a poor
261 job and I could relate this to the example of the robot controller causing the robot
262 to spin in circles when the IMU is giving faulty outputs. Note that this would not
263 be a sufficient condition to show that the controller is performing properly but
264 would only be an indication that the KF output needs improvement. There are
265 likely ways of assessing controller performance if the KF output variance is large
266 though. ***

267 **Chapter 6**

268 **Future Work**

269 *** Suggest avenues of study for future work. ***

270 **Chapter 7**

271 **Conclusion**

272 *** Summarize the results here. ***

273 **Appendix A**

274 **Source Code**

275 *** Put source code here if applicable. Consider putting a list of Acronyms in
276 an appendix. ***
